

ABSTRACT

The setup data from a source application or computer may be accessed and used to supplant the setup data from a destination application or computer, and the supplanted setup data may be preserved for reinstatement or future access. The supplanting setup data may be stored in a data store that is accessible to the destination, and may be local or remote to either or both of the source and destination. When the setup data is used to supplant data within a destination application, the incumbent setup data from that destination application may be stored in the data store, such that the data store includes first application setup data derived from one or more source software applications and second application setup data obtained based on application setup data that has been supplanted with one or more of the first application setup data.
